Zanimivosti

Python funkcije so objekti. Lahko jih shranimo v spremenljivke, lahko jih posredujemo kot argumente ali vrnemo kot vrednost funkcije.

In [100]:

```
def hello(name):
    return f'My name is {name}'
```

In [101]:

```
print(hello("Gregor"))
```

```
My name is Gregor
```

In [102]:

```
funkcija = hello
print(funkcija("Gregor"))
print(funkcija)
print(type(funkcija))
```

```
My name is Gregor
<function hello at 0x0000015411EE6A60>
<class 'function'>
```

In [103]:

```
func = [hello, 2 ,3, 'Janez']
print(func[0](func[3]))
```

```
My name is Janez
```

In [ ]:

```

```

Naloga:

Ustvarite funkcijo, ki kot parametra vzeme list številk in neko število **m**, ki predstavlja zgornjo mejo.

Funkcija naj se sprehodi skozi podan list in vsako število, ki je večje od m, spremeni v m.

Funkcija naj na koncu vrne spremenjen list.

Primeri:

```
Input:
funkcija([1,12,-3,54,12,-22,65,32], 33)

Output:
[1, 12, -3, 33, 12, -22, 33, 32]
```

In [ ]:

```
```

Naloga:

Ustvari funkcijo, ki uredi list po vrstnem redu. Sprejme naj list in ukaz **asc** (naraščajoči vrstni red) ali **desc** (padajoči vrstni red). List naj nato ustrezno uredi. V kolikor ukaz ni posredovan naj bo default vrednost **asc**.

Primeri:

```
Input:
fun_03([1,4,2,8,4,0], ukaz="desc")

Output:
[8, 4, 4, 2, 1, 0]

Input:
fun_03([1,4,2,8,4,0], ukaz="asc")

Output:
[0, 1, 2, 4, 4, 8]

Input:
fun_03([5,8,-2,13,6,-6])

Output:
[-6, -2, 5, 6, 8, 13]
```

In [ ]:

```
```

In [ ]:

```
```

In [ ]:

```
```

Lambda funkcija

Lambda funkcije so anonimne funkcije, kar pomeni, da nimajo imena (niso vezane na spremenljivko).

> Anonimna funkcija - anonymous function is a function that is defined without a name.

> We have already seen that when we want to use a number or a string in our program we can either write it as a literal in the place where we want to use it or use a variable that we have already defined in our code. For example, print("Hello!") prints the literal string "Hello!", which we haven't stored in a variable anywhere, but print(message) prints whatever string is stored in the variable message.

> We have also seen that we can store a function in a variable, just like any other object, by referring to it by its name (but not calling it). Is there such a thing as a function literal? Can we define a function on the fly when we want to pass it as a parameter or assign it to a variable, just like we did with the string "Hello!"?

> A lambda function may only contain a single expression, and the result of evaluating this expression is implicitly returned from the function (we don't use the return keyword)

```
lambda x,y : x +y
```

Sestavljene so iz:

- lambda - keyword
- parametri so napisani med lambda in :
- "single expression" (1 vrstica kode). Rezultat / vrednost tega "single expression" se vrne kot vrednost funkcije

In [1]:

```
(lambda x, y: x+y)(2, 3)
```

Out[1]:

```
5
```

In [2]:

```
add = lambda x, y: x + y
print(add)
print(type(add))
```

```
<function <lambda> at 0x000001D590FDDE50>
<class 'function'>
```

In [5]:

```
add(5,3)
```

Out[5]:

```
8
```

Primer, če bi zgornjo lambda funkcijo napisalo kot navadno funkcijo.

In [6]:

```
def add(x, y):
    return x + y
```

In [ ]:

```

```

Lambda funkcije pridejo najbolj do izraza, kjer je treba kot argument posredovati funkcijo. Namesto dejanske funkcije lahko posredujemo lambda funkcijo.

Za primer vzemimo funkcijo `sorted()` .

Naša naloga je sortirati sledeče vrednosti glede na **market_cap** vrednost, od največje do najmanjše.

In [13]:

]
```

https://docs.python.org/3/library/functions.html#sorted (https://docs.python.org/3/library/functions.html#sorted)

```
sorted(iterable, *, key=None, reverse=False)
```

V dokumentaciji vidimo, da lahko kontroliramo katere vrednosti primerjamo z uporabo **key** parametra.

Kot **key** lahko podamo našo funkcijo, ki sprejme 1 argument in vrne vrednost po kateri primerjamo.

In [22]:

```
def sort_funkcija(x):
    print(f'{x["id"]}    \t {x["market_cap"]}')
    return x["market_cap"]

sorted(data, key=sort_funkcija, reverse=True)
```

Generators

Generatorji so funkcije namenjene generiranju iteratorjev (objekti, ki so lahko iterirani - list, itd..).

Razlika je, da generatorji generiranjo vrednosti eno po eno, ne vse naenkrat, kar jih nrdi veliko bolj memory-efficient.

Ustvarimo jih enako kot navadno funkcijo, le da namesto `return` uporbimo `yield` .

`yield` pavzira funkcijo in shrani njeno stanje, tako da lahko kasneje nadaljujemo kjer smo končali.

In [57]:

```
def moj_range(n):
    print("Start creating moj range")
    while n<10:
        yield n
        n += 1
    print("Stop generator")

val = moj_range(5)
print(val)
print(type(val))
```

```
<generator object moj_range at 0x000001D59110D740>
<class 'generator'>
```

Ko prvič pokličemo `next()` se program začne izvajati na začetku funkcije in nadaljuje do `yield` kjer vrne vrednost.

Naslednji klici `next()` nadaljujejo izvajanje programa od `yield` naprej do naslednjega `yield` .

Če ne naleti na `yield` dvigne StopIteration exception.

In [58]:

```
print(next(val))
```

```
Start creating moj range
5
```

In [59]:

```
next(val)
```

Out[59]:

```
6
```

In [60]:

```
next(val)
```

Out[60]:

```
7
```

In [61]:

```
#val = moj_range(5) # Če vmes ponovno kličemo generator bo šlo od začetka.
```

In [62]:

```
next(val)
```

Out[62]:

```
8
```

In [63]:

```
next(val)
```

Out[63]:

```
9
```

In [64]:

```
next(val)
```

```
Stop generator

---------------------------------------------------------------------------
StopIteration                             Traceback (most recent call
 last)
<ipython-input-64-a2a2bf9708c5> in <module>
----> 1 next(val)

StopIteration:
```

Z generatorjem lahko ustvarimo svojo `range()` funkcionalnost.

In [67]:

```
def moj_range(n, m, step=1):
    while n<m:
        yield n
        n+=step

print("Primer: moj_range")
for i in moj_range(1, 20, 2):
    print(i)

print("Primer: range()")
for i in range(1, 20, 2):
    print(i)
```

```
Primer: moj_range
1
3
5
7
9
11
13
15
17
19
Primer: range()
1
3
5
7
9
11
13
15
17
19
```

In [ ]:

```

```

Comprehensions

Poleg generatorjev, lahko za kreiranje listov uporabimo tudi **list comprehensions**.

- List comprehensions so bolj berljivi od built-in funkcij, ki potrebujejo lambda expressions
- List comprehensions nam dovolijo filtriranje elementov

In [69]:

```
# Primer: želimo narediti list kvadratov iz lista a
a = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
squares = [x**2 for x in a]
print(a)
print(squares)
```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
[1, 4, 9, 16, 25, 36, 49, 64, 81, 100]
```

In [70]:

```
# Primer: Filtriranje elementov
a = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13]

even_squares = [x**2 for x in a if x%2 == 0 and x%3==0]
print(a)
print(even_squares)
```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13]
[36, 144]
```

set comprehensions

In [85]:

```
a = {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
even_squares = {x**2 for x in a if x % 2 == 0}
print(even_squares)
print(type(even_squares))
```

```
{64, 100, 4, 36, 16}
<class 'set'>
```

Dictionary Comprehensions

```
ict_variable = {key:value for (key,value) in dictonary.items()}
```

In [86]:

```
dict1 = {'a': 1, 'b': 2, 'c': 3, 'd': 4, 'e': 5}
# Double each value in the dictionary
double_dict1 = {k:v*2 for (k,v) in dict1.items()}
print(double_dict1)
```

```
{'a': 2, 'b': 4, 'c': 6, 'd': 8, 'e': 10}
```

Generator Expressions

Podobno kot list comprehensions lahko zapišemo tudi generatorje. Razlika je, da oni vrnejo generator objekt in ne list-e.

In [71]:

```
import sys

my_list = ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j']

list_comprehension = [x for x in my_list]
set_comprehension = {x for x in my_list}
gen_expression = (x for x in my_list) # the language name for these is generator ex

print(list_comprehension)
print(type(list_comprehension))
print(sys.getsizeof(list_comprehension))
print()

print(set_comprehension)
print(type(set_comprehension))
print(sys.getsizeof(set_comprehension))
print()

print(gen_expression)
print(type(gen_expression))
print(sys.getsizeof(gen_expression))
for val in gen_expression:
    print(val)
```

```
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j']
<class 'list'>
184

{'d', 'j', 'f', 'g', 'i', 'a', 'b', 'c', 'e', 'h'}
<class 'set'>
728

<generator object <genexpr> at 0x000001D5910FE900>
<class 'generator'>
112
a
b
c
d
e
f
g
h
i
j
```

Glavna razlika med `generator expressions` in `list comprehension` je, da so generatorji počasnejši ampak prišparajo na spominu.

Variable scope

Spremenljivke se razlikujejo tudi po tem koliko dolgo obstajajo (variable lifetime) in od kje lahko dostopamo do njih (variable scope).

Spremenljivka definirana znotraj funkcije (kot parameter ali navadno) obstaja samo znotraj funkcije.

Ko se izvajanje funkcije konča, spremenljivka neha obstajati.

In [72]:

```
def funkcija(spr1):
    spr2 = 10
    print(f"Spr1: {spr1}")
    print(f"Spr2: {spr2}")

funkcija(5)
print(f"Spr1: {spr1}")
print(f"Spr2: {spr2}")
```

```
Spr1: 5
Spr2: 10

---------------------------------------------------------------------
-----
NameError                                 Traceback (most recent call
 last)
<ipython-input-72-d9649ca9516e> in <module>
      6
      7 funkcija(5)
----> 8 print(f"Spr1: {spr1}")
      9 print(f"Spr2: {spr2}")

NameError: name 'spr1' is not defined
```

Spremenljivka definirana znotraj naše glavne kode (zunaj naših funkcij) je **globalna spremenljivka** in je dostopna skozi našo celotno kodo.

In [73]:

```
spr1 = 5
print(f"Spr1: {spr1}")

if spr1 == 5:
    spr2 = 10
print(f"Spremenljivka2: {spr2}")
print()

def funkcija():
    spr3 = 200
    print(f"Spr1: {spr1}")
    print(f"Spr2: {spr2}")
    print(f"Spr3: {spr3}")

funkcija()
print()

print(f"Spr1: {spr1}")
print(f"Spr2: {spr2}")
```

```
Spr1: 5
Spremenljivka2: 10

Spr1: 5
Spr2: 10
Spr3: 200

Spr1: 5
Spr2: 10
```

Problem se lahko pojavi, če znotraj funkcije definiramo spremenljivko z enakim imenom, ki že obstaja kot globalna spremenljivka.

V tem primeru bo python spremenljivki označil kot dve različni spremenljivki. Ena dostopna znotraj funkcije, druga dostopna zunaj funkcije.

In [164]:

```
spr1 = 5
print(f"Spr1: {spr1}")

def funkcija():
    spr1 = 100
    print(f"Spr1: {spr1}")

funkcija()
print(f"Spr1: {spr1}")
```

```
Spr1: 5
Spr1: 100
Spr1: 5
```

Parameter se obnaša kot lokalna spremenljivka.

In [175]:

```
spr1 = 5
print(f"Spr1: {spr1}")

def funkcija(spr1):
    print(f"Spr1: {spr1}")

funkcija(100)
print(f"Spr1: {spr1}")
```

```
Spr1: 5
Spr1: 100
Spr1: 5
```

Paziti je potrebno, ko posredujemo list ali dictionary kot argument.

In [74]:

```
def funkcija(l):
    print(l)
    l[0] = 100

seznam = [3, 7, 13]
funkcija(seznam)
print(seznam)
```

```
[3, 7, 13]
[100, 7, 13]
```

In [75]:

```
def funkcija(d):
    print(d)
    d["a"] = 100

dict_ = {"a": 5, "b": 6, "c": 7}
funkcija(dict_)
print(dict_)
```

```
{'a': 5, 'b': 6, 'c': 7}
{'a': 100, 'b': 6, 'c': 7}
```

In [ ]:

```

```

Če želimo spreminjati globalno spremenljivko znotraj funkcije (znotraj local scope) moramo uporabiti besedo **global**.

In [76]:

```
spr1 = 5
print(f"Spr1: {spr1}")

def funkcija():
    global spr1
    spr1 = 100
    print(f"Spr1: {spr1}")

funkcija()
print(f"Spr1: {spr1}")
```

```
Spr1: 5
Spr1: 100
Spr1: 100
```

S to besedo lahko tudi ustvarimo novo globalno spremenljivko, znotraj localnega scopa.

In [77]:

```
def funkcija():
    global spr1
    spr1 = 5
    print(f"Spr1: {spr1}")

funkcija()
print(f"Spr1: {spr1}")
```

```
Spr1: 5
Spr1: 5
```

In [ ]:

```

```

Naloga:

Napišite funkcijo, kjer lahko igramo **vislice**.

Funkcija **vislice()** naj ima 2 parametra. Prvi je besedo katero se ugiba in drugi število možnih ugibov. Če števila ugibov ne podamo naj bo default vrednost 10.

Uporabnika konstantno sprašujte naj vnese črko. Nato izpišite iskano besedo. Črke katere je uporabnik uganil izpišite normalno, črke katere še ni uganil pa nadomestite z _.

Dodatno zraven prikazujte katere vse črke je uporabnik že preizkusil.

Če uporabnik besedo uspešno ugani v danih poizkusih naj funkcija vrne vrednost True. V nasprotnem primeru naj vrne vrednost False.

Primeri:

```
Input:
vislice("jabolko")

Output:
Guesses so far [].
What is your guess? a
_ a_ _ _ _ _

Guesses so far ['a'].
What is your guess? e
_ a_ _ _ _ _

Guesses so far ['a', 'e'].
What is your guess? o
_ a_ o_ _ o

Guesses so far ['a', 'e', 'o'].
What is your guess? p
_ a_ o_ _ o

Guesses so far ['a', 'e', 'o', 'p'].
What is your guess? r
_ a_ o_ _ o

Guesses so far ['a', 'e', 'o', 'p', 'r'].
What is your guess? l
_ a_ ol_ o

Guesses so far ['a', 'e', 'o', 'p', 'r', 'l'].
What is your guess? k
_ a_ olko

Guesses so far ['a', 'e', 'o', 'p', 'r', 'l', 'k'].
What is your guess? j
ja_ olko

Guesses so far ['a', 'e', 'o', 'p', 'r', 'l', 'k', 'j'].
What is your guess? b
jabolko
KONEC
True
```

In [ ]:

```
```

In [ ]:

```
```

Naloga:

Ustvarite program **Križci in Krožci**

Igralno polje lahko predstavite kot liste znotraj lista, kjer *E* predstavlja prazno polje.

```
board = [["X", "E", "E"],
         ["O", "E", "E"],
         ["E", "E", "E"]]
```

Od igralcev nato izmenično zahtevajte polje v katerega želijo postaviti svoj znak. Privzememo lahko, da bodo igralci igrali pravično in vpisovali samo prazna polja.

Primeri:

```
Output:
['E', 'E', 'E']
['E', 'E', 'E']
['E', 'E', 'E']
It's X's turn. Make a move (exp: 12): '00

['X', 'E', 'E']
['E', 'E', 'E']
['E', 'E', 'E']
It's O's turn. Make a move (exp: 12): '12

['X', 'E', 'E']
['E', 'E', 'O']
['E', 'E', 'E']
It's X's turn. Make a move (exp: 12): '10

['X', 'E', 'E']
['X', 'E', 'O']
['E', 'E', 'E']
It's O's turn. Make a move (exp: 12): '12

['X', 'E', 'E']
['X', 'E', 'O']
['E', 'E', 'E']
It's X's turn. Make a move (exp: 12): '20
X je ZMAGOVALEC!
```
